The protrusions observed in the AFM images are confirmed as energy-packet group for three reasons, protrusions move ~1 μm per minute, (400 km/hour). Energy-packet density is obtained by counting total number of energy-packet groups (not individual energy-packets) divided by the area scanned, considering 50% visibility as absolute. We calculate periodicity  $\lambda$  for using  $\lambda = \pi/k_F$ , where, wave vector  $k_F = \pi/na$ , where  $a$  is the lattice parameter, 8 nm, and  $1/n$  is the band filling. Mass of energy-packet has been calculated by using the formulae  $M_s = (4/3l)(u_0/a)^2 M$ , where  $u_0$  is the lattice distortion,  $M$  is the mass of 3 tubulin monomers capturing a defect site or point of asymmetry,  $2l$  is energy-packet length,  $a$  is lattice parameter,  $M_s \sim 300$  me for phonon energy-packet periodicity 3. Even though electronic energy-packet has mass  $M_s \sim 15$  me, statistically, phonon energy-packet periodicity 3, reflects synchrony accurately, so we ignore electronic mass.
